

# Simplicial Homology

Jan Philipp Zwank

Seminar: Topology vs. Combinatorics WS 2018/19

Handed in: 31.10.2018

Presentation: 07.11.2018

*ABSTRACT. Simplicial homology is a valuable tool for distinguishing polyhedra. We achieve that by assigning an abelian groups  $H_n(X; G)$  to the underlying simplicial complex of the polyhedron  $|X|$ . We call these groups the Homology groups of  $X$  with coefficients in  $G$ , where  $G$  is an abelian Group. As we will see, simplicial homology is in fact a functor from the category of simplicial complexes to the category of abelian groups. In addition, we will see that Homology groups only depend on the homotopy type, i.e. two spaces that are homotopy equivalent have isomorphic Homology groups.*

## 1 Motivation

One of the main goals when studying (topological) spaces (or in this case simplicial complexes) is to determine whether two spaces are homeomorphic or at least homotopy equivalent (see Definition 5.3) or not. The first approach would be to check if both spaces are simply connected. A more advanced method checks if the fundamental groups  $\pi_1$  coincide<sup>1</sup>.

It turns out that this is a valuable tool for one and two dimensional simplicial complexes. But this method fails for complexes with higher dimensional simplices. For example  $\pi_1(\mathbb{S}^n) = 0$  for all  $n \geq 2$ . It is therefore impossible to show that two spheres of dimension greater or equal 2 are only then homeomorphic if they are of the same dimension. It can be shown that the fundamental group actually only depends on the 2-skeleton of the complex [vgl. 1, p. 173].

Even though this method can be generalized to the study of higher homotopy groups  $\pi_n$ , this is often more difficult than necessary since the computation of those groups is far from trivial.

In the following we will explore the concept of simplicial homology groups and how it can be used to classify spaces. We will see that they allow us to tackle the problem of deciding whether two **polyhedra**<sup>2</sup> are homeomorphic. Note that isomorphic Homology classes do not automatically mean that the spaces are homeomorphic. In fact the torus  $T$  and  $\mathbb{S}^1 \wedge \mathbb{S}^1$  have the same homology groups in every dimension but they are not homeomorphic ( $\pi_1(T) = \mathbb{Z} \oplus \mathbb{Z}$  whereas  $\pi_1(\mathbb{S}^1 \wedge \mathbb{S}^1) = \mathbb{Z} * \mathbb{Z}$ ).

It is possible to extend the concept of Homology to more general spaces than polyhedra using singular homology, however those will not be covered here. The interested reader might refer to the book of Munkres [4] or Hatcher [3] to learn more about singular homology groups.

While we considered all possible paths when we were talking about the fundamental group we will now only consider those that aren't the boundary of a portion of the surface. A great motivation for this approach is given by Armstrong [1, p. 173f]:

When we concern ourselves with the question how closed paths on the torus are different from those on the sphere, we can notice the following: Any Jordan curve (i.e. nonselfintersecting, closed path) on a sphere divides the surface into two „regions“ as depicted in Figure 1<sup>3</sup>. The same is not true for the torus. In Figure 2 we see that even

<sup>1</sup>The fundamental group  $\pi_1(X)$  is the group of all closed paths with the group action being concatenation.

If  $X$  is a simply connected space then  $\pi_1(X) = 0$ . Furthermore, the fundamental group is homotopy invariant (up to isomorphism), so homotopic spaces have isomorphic fundamental groups. A more precise formulation of this statement can be found in Hatcher's book [3, Prop. 1.18, p. 37]:

If  $\phi : X \rightarrow Y$  is a homotopy equivalence, then it induces homomorphism  $\phi_* : \pi_1(X, x_0) \rightarrow \pi_1(Y, \phi(x_0))$  is an isomorphism for all  $x_0 \in X$ .

<sup>2</sup>A polyhedron is the polytope of a simplicial complex.

<sup>3</sup>For a more precise statement see [https://en.wikipedia.org/wiki/Jordan\\_curve\\_theorem](https://en.wikipedia.org/wiki/Jordan_curve_theorem)

tough there are Jordan curves on a torus that bound a „region“ of the surface, not all Jordan curves have that property [see 1, p. 173f].

Figure 1: Any closed path on the sphere divides the surface into two regions.

Figure 2: There are closed paths on the torus that do not divide the surface into two regions.

## 2 Simplicial Homology Groups with Integer Coefficients

Before we get started, let us remind ourselves of some definitions and notations as can be found in Munkres' book [4, p. 26f.]

**Definition 2.1.** For a simplex  $\sigma$  we say that two orderings of its vertex set are equivalent if they differ by an even permutation. For a simplex with nonzero dimension, the orderings of the vertices fall into two equivalence classes, called the **orientations** of  $\sigma$ . An **oriented simplex** is a simplex together with an orientation.

Further we will use the same notation as Munkres [4, p. 26]

**Notation 2.2.** For geometrically independent points  $v_0, \dots, v_p$  we denote the simplex they span with

$$[v_0, \dots, v_p].$$

For an oriented simplex we will use the notation

$$(v_0, \dots, v_p).$$

where the orientation is given by this particular ordering.

A choice of orientation is usually depicted with arrows as can be seen in Figure 3

To define simplicial homology groups in any meaningful way, we need a few definitions that allow us to formulate our ideas from section 1 more precise. There are several ways to go about this. We will follow the path of Munkres [4, p. 27] here.

Figure 3: Indicating orientation with arrows [see 4, p.27]

**Definition 2.3.** Let  $K$  be a simplicial complex. A  $p$ -**chain** on  $K$  is a function  $c$  from the set of oriented  $p$ -simplices of  $K$  to the integers such that:

1.  $c(\sigma) = -c(\sigma')$  if  $\sigma$  and  $\sigma'$  are opposite orientations of the same simplex.
2.  $c(\sigma) = 0$  for all but finitely many oriented  $p$ -simplices  $\sigma$ .

We add  $p$ -chains by adding their values; the resulting group is denoted  $C_p(K)$  and is called the group of (oriented)  $p$ -chains of  $K$ . If  $p < 0$  or  $p > \dim K$ , we let  $C_p(K)$  denote the trivial group.

If  $\sigma$  is an oriented simplex, the elementary chain  $c_\sigma$  corresponding to  $\sigma$  is the function defined as follows:

$$\begin{aligned} c_\sigma(\sigma) &= 1, \\ c_\sigma(\sigma') &= -1 && \text{if } \sigma' \text{ is the opposite orientation of } \sigma \\ c_\sigma(\tau) &= 0 && \text{for all other oriented simplices } \tau. \end{aligned}$$

It is common practice to abuse the notation here in the following way: If clear by context we use the symbol  $\sigma$  not only to denote the (oriented) simplex, but also the corresponding elementary chain.

We are now able to formulate our first result as can be found in Munkres book [4, Lemma 5.1, p. 28]:

**Lemma 2.4.**  $C_p(K)$  is free abelian.

*Proof.* A basis for  $C_p(K)$  can be obtained by orienting each  $p$ -simplex and using the corresponding elementary chains as a basis. It is easy to see that each chain  $c$  in  $C_p(K)$  can be expressed uniquely as a linear combination of the elementary chains  $c_{\sigma_i}$  of the simplices of  $K$ , i.e.

$$c = \sum_i n_i c_{\sigma_i}.$$

Here, the chain  $c$  assigns the value  $n_i$  to each simplex  $\sigma_i$ ,  $-n_i$  for the simplex  $\sigma_i$  with reversed orientation and 0 to every simplex that does not appear in the summation.<sup>4</sup>  $\square$

Some authors such as Armstrong [1, p.176f] or Ferrario [2, p.60] prefer to introduce chains as formal linear combinations of simplices. By virtue of the lemma above, it is clear that the definitions are analog.

**Definition 2.5.** We define the boundary operator

$$\partial_p : C_p(K) \rightarrow C_{p-1}(K)$$

to be the homomorphism via its action on an elementary chain corresponding to an oriented simplex  $\sigma = (v_0, \dots, v_p)$ :

$$\partial_p \sigma = \partial_p(v_0, \dots, v_p) = \sum_{i=0}^p (-1)^i (v_0, \dots, \hat{v}_i, \dots, v_p)$$

where the symbol  $\hat{v}_i$  means that the vertex  $v_i$  is to be deleted from the array.

As the name suggests, the result of this homomorphism indeed refers to the (topological) boundary of the simplex once we interpret the sum of two elementary chains as the union of the corresponding simplices as we will see in several examples 2.6. But first we have to check well-definedness. For that, it is necessary to show that

$$\partial_p(-\sigma) = -\partial_p(\sigma)$$

Since the orientation of a simplex only depends on the *sign* of the permutation, it is sufficient to check for the simple case of exchanging  $v_0$  and  $v_1$ :

$$\begin{aligned} & \partial_p(v_0, \dots, v_p) + \partial_p(v_1, v_0, v_2, \dots, v_p) \\ &= (v_1, \dots, v_p) - (v_0, v_2, \dots, v_p) + \sum_{i=2}^p (-1)^i (v_0, \dots, \hat{v}_i, \dots, v_p) \\ &+ (v_0, v_2, \dots, v_p) - (v_1, v_2, \dots, v_p) + \sum_{i=2}^p (-1)^i \underbrace{(v_1, v_0, v_2, \dots, \hat{v}_i, \dots, v_p)}_{=-(v_0, v_1, v_2, \dots, \hat{v}_i, \dots, v_p)} = 0 \end{aligned}$$

---

<sup>4</sup>Recall that by definition of the elementary chains we have

$$c_{\sigma_i}(\tau) = \begin{cases} 1 & \text{if } \sigma_i = \tau \\ -1 & \text{if } \tau \text{ is the opposite orientation of } \sigma_i \\ 0 & \text{else} \end{cases}$$

**Examples 2.6.**

$$1. \partial_1(v_0, v_1) = v_1 - v_0$$

$$\bullet v_1 - \bullet v_0$$

$$2. \partial_2(v_0, v_1, v_2) = (v_1, v_2) - (v_0, v_2) + (v_0, v_1)$$

$$3. \partial_3(v_0, v_1, v_2, v_3) = (v_1, v_2, v_3) - (v_0, v_2, v_3) + (v_0, v_1, v_3) - (v_0, v_1, v_2)$$

Recall the following definition of a chain complex as can be found in Munkres' book<sup>5</sup>[4, p. 71]:

**Definition 2.7.** A chain complex  $\mathcal{C}$  is a family  $\{C_p, \partial_p\}$  of abelian groups  $C_p$  and homomorphisms

$$\partial_p : C_p \rightarrow C_{p-1}$$

indexed with integers, such that  $\partial_p \circ \partial_{p-1} = 0$  for all  $p$ .

**Lemma 2.8.**  $\{C_\bullet, \partial\}$  is a chain complex.

*Proof.* We need to show that  $\partial_{p-1} \circ \partial_p \equiv 0$ . It is not hard to prove this, it just requires some bookkeeping:

<sup>5</sup>One can find an alternative definition in Ferrario's book[2, p. 65]

A chain complex  $(\mathcal{C}_\bullet, \partial')$  is a graded abelian group  $\{\mathcal{C}_n\}$  together with an endomorphism  $\partial' = \{\partial'_n\}$  of degree  $-1$  such that  $(\partial')^2 = 0$ . Where we say that an endomorphism  $d$  has degree  $k$  if  $d(C_k) \subset C_{k+d}$ .

It is easy to see that these definitions are essentially the same even though they look quite different.

Let  $\sigma = (v_0, \dots, v_p)$  be an arbitrary  $p$ -chain, then

$$\begin{aligned} \partial_{p-1} \circ \partial_p(\sigma) &= \partial_{p-1} \left( \sum_{i=0}^p (-1)^i (v_0, \dots, \hat{v}_i, \dots, v_p) \right) = \sum_{i=0}^p (-1)^i \partial_{p-1}(v_0, \dots, \hat{v}_i, \dots, v_p) \\ &= \sum_{i=0}^p (-1)^i \sum_{\substack{j=0 \\ j \neq i}}^p (-1)^j (v_0, \dots, \hat{v}_j, \dots, \hat{v}_i, \dots, v_p) \end{aligned}$$

Each of these term shows up twice with different signs. Thus, everything cancels.  $\square$

A common question for chain complexes is exactness. As we will see later in this chapter,  $\{C_\bullet, \partial\}$  will only be exact for very special cases. The following definition is taken from Munkres' book [4, p. 72] and will be needed later on.

**Definition 2.9.** Let  $\mathcal{C}$  and  $\mathcal{C}'$  be chain complexes. A chain map  $\Phi : \mathcal{C} \rightarrow \mathcal{C}'$  is a family of homomorphisms

$$\Phi_p : C_p \rightarrow C'_p$$

such that  $\partial'_p \circ \Phi_p = \Phi_{p-1} \circ \partial_p$  for all  $p$ .

Before we define the simplicial homology groups, we will introduce one more definition:

**Definition 2.10.**

1. The kernel of  $\partial_p : C_p(K) \rightarrow C_{p-1}(K)$  is called the group of  $p$ -cycles and denoted by  $Z_p(K)$ .
2. The image of  $\partial_{p+1} : C_{p+1}(K) \rightarrow C_p(K)$  is called the group of  $p$ -boundaries and is denoted  $B_p(K)$ .

The previous lemma states that  $B_p(K) \subset Z_p(K)$ .

Let us remind ourselves of what we wanted to do in section 1. We wanted to consider those closed curves (*cycles*) that were not the *boundary* of some part of the surface. With this in mind, we can now state the definition of simplicial homology groups

**Definition 2.11.** We define

$$H_p(K) := Z_p(K) / B_p(K) = \ker \partial_p / \text{Im } \partial_{p+1}$$

and call it the **p-th simplicial homology group of K**.

**Examples 2.12.**

1. Let us begin with the easiest example one can think of. Let  $K$  be the simplicial complex consisting of only one 0-simplex (i.e. one vertex  $v$ ). Clearly the chain complex then reads

$$\begin{array}{ccccc}
C_1(K) & \xrightarrow{\partial} & C_0(K) & \xrightarrow{\partial} & 0 \\
\parallel & & \parallel & & \parallel \\
0 & \xrightarrow{\partial} & \mathbb{Z}\langle v \rangle & \xrightarrow{\partial} & 0
\end{array}$$

Then the homology groups are

$$H_0(K) \cong \mathbb{Z}, \quad H_{n>1}(K) = 0$$

2. We will now consider the circle. This can be triangulated as an empty triangle, i.e.

We easily find

$$\partial_1 = \begin{bmatrix} -1 & 0 & 1 \\ 1 & -1 & 0 \\ 0 & 1 & -1 \end{bmatrix}, \quad \partial_0 \equiv 0$$

Therefore,

$$H_1(\mathbb{S}^1) \cong \mathbb{Z}/0 \cong \mathbb{Z}, \quad H_0(\mathbb{S}) \cong \mathbb{Z}^3/\mathbb{Z}^2 \cong \mathbb{Z}$$

We will consider the (more interesting) cases of the torus and the Klein Bottle shortly. But we need a preliminary result first because even though the same method as before can be applied in theory, this is not very practical since the matrices would uncomfortably large.

**Lemma 2.13.** *Let  $L$  be the complex depicted in figure 4, whose underlying space is a rectangle. Let  $\text{Bd}L$  denote the complex whose space is the boundary of the rectangle. Orient each 2-simplex  $\sigma_i$  of  $L$  counterclockwise. Orient the 1-simplices arbitrarily. Then:*

1. *Every 1-cycle of  $L$  is homologous to a 1-cycle carried by  $\text{Bd}L$ .*
2. *If  $d$  is a 2-chain of  $L$  and if  $\partial d$  is carried by  $\text{Bd}L$ , then  $d$  is a multiple of the chain  $\sum \sigma_i$ .*

Figure 4: Complex whose underlying space is a rectangle.

Figure 5: Structure of center. 2-simplices are oriented counterclockwise

*Proof.* We will prove the second statement first. If  $\sigma_i$  and  $\sigma_j$  have an edge  $e$  in common, then  $\partial d$  must have value 0 on  $e$ . It follows that  $d$  must have the same value  $\sigma_i$  as it does in  $\sigma_j$ . Continuing this process, we see that  $d$  has the same value on every oriented 2-simplex  $\sigma_i$ .

For the second part, let  $c$  be a 1-chain of  $L$ . We will „push it off “ the 1-simplices in the following way:

We concentrate on the center at first. There we notice the structure as depicted in figure 5.

Let  $c$  denote a 1-chain with value  $a$  on  $e_1$ . Then  $c$  is clearly homologous to the chain  $c_1 = c + \partial(a\sigma_1)$ . The resulting 1-chain  $c_1$  vanishes on  $e_1$ . We have „pushed it off“  $e_1$ . We can apply this multiple times for other edges until we arrive at a chain  $c_2$  which is carried by the subcomplex depicted in figure 6

Since our original  $c$  is a cycle,  $c_2$  must be carried by  $\text{Bd}L$ , because otherwise  $\partial c_2$  would have non-zero coefficients on one or more of the vertices  $v_1, \dots, v_5$ .  $\square$

**Theorem 2.14.** *Let  $T$  denote the complex represented by the labeled rectangle  $L$  of Figure 7. Its underlying space is the torus. Then:*

$$H_1(T) \cong \mathbb{Z} \oplus \mathbb{Z} \quad \text{and} \quad H_2(T) \cong \mathbb{Z}.$$

Figure 6: Subcomplex that carries  $c_2$ .

Figure 7: Labeled Complex whose underlying space is a torus.

*Orient each 2-simplex of  $L$  counterclockwise; use the induced orientation of the 2-simplices of  $T$ ; Let  $\gamma$  denote their sum. Let*

$$\begin{aligned} w_1 &= [a, b] + [b, c] + [c, a], \\ z_1 &= [a, d] + [d, e] + [e, a]. \end{aligned}$$

*Then  $\gamma$  generates  $H_2(T)$  and  $w_1$  and  $z_1$  represent a basis for  $H_1(T)$ .*

*Proof.* Let  $g : |L| \rightarrow |T|$  be the pasting (gluing) map; let  $A = g(|\text{Bd}L|)$ . Then  $A$  is homeomorphic to<sup>6</sup>  $\mathbb{S}^1 \wedge \mathbb{S}^1$  as depicted in figure 8. Orient the 1-simplices of  $T$  arbitrarily. Since  $g$  only identifies simplices in  $\text{Bd}L$ , we find the same statements as above with identical arguments.

1. Every 1-cycle of  $T$  is homologous to a 1-cycle carried by  $A$ .
2. If  $d$  is a 2-chain of  $T$  and if  $\partial d$  is carried by  $A$ , then  $d$  is a multiple of  $\gamma$ .

Additionally, we find here

---

<sup>6</sup>The wedge sum is the disjoint union where two points are identified.

Figure 8:  $A$  is homeomorphic to  $\mathbb{S}^1 \wedge \mathbb{S}^1$ 

3. If  $c$  is a 1-cycle of  $T$  carried by  $A$ , then  $c$  is of the form  $nw_1 + mz_1$ .
4.  $\partial\gamma = 0$ .

The statement in item 3 is clear by looking at figure 8. For item 4 we need to see the following: It is clear that  $\partial\gamma$  vanishes on any 1-simplex not contained in  $A$ . By direct computation one can see that  $\partial\gamma$  also vanishes on all 1-simplices in  $A$ . The 1-simplex  $[a, b]$  appears as a face of  $\sigma_1$  and  $\sigma_2$  and no other simplices. If we evaluate  $\partial\sigma_1$  the elementary chain  $[a, b]$  is assigned the value  $-1$  and evaluating  $\partial\sigma_2$  gives  $+1$  for  $[a, b]$ .

Combining all of the results above yields the homology groups of  $T$ : Every 1-cycle of  $T$  is homologous to a 1-cycle of the form  $c = nw_1 + mz_1$  by 1 and 3. Such a cycle bounds only if it is trivial: If  $c = \partial d$  for some  $d$ , then by virtue of 2  $d = p\gamma$  for some integer  $p$ . By 4 we know that  $\partial\gamma = 0$ , so  $c = 0$ . Therefore,

$$H_1(T) \cong \mathbb{Z} \oplus \mathbb{Z};$$

with base elements  $w_1$  and  $z_1$ .

For dimension 2, we find that any 2-cycle  $d$  of  $T$  must be of the form  $p\gamma$  for some  $p$  by virtue of 2. Such a 2-chain is always a cycle, by 4, and there are no 3-chains whose boundary they could be, hence

$$H_2(T) \cong \mathbb{Z}$$

with generator  $\gamma$ . □

**Theorem 2.15.** *let  $S$  denote the complex represented by the labeled rectangle of figure 9; its underlying space is the Klein bottle. Then*

$$H_1(S) \cong \mathbb{Z} \oplus \mathbb{Z}_2 \quad \text{and} \quad H_2(S) = 0.$$

*The torsion element of  $H_1(S)$  is represented by the chain  $z_1$ , and a generator for the group  $H_1(S)$  modulo torsion is represented by  $w_1$ , where*

$$\begin{aligned} w_1 &= [a, b] + [b, c] + [c, a] \\ z_1 &= [a, d] + [d, e] + [e, a]. \end{aligned}$$

Figure 9: Labeled Complex whose underlying space is the Klein bottle.

*Proof.* Let  $g$  and  $A$  be as before with the obvious changes. Again,  $A$  is homeomorphic to  $\mathbb{S}^1 \wedge \mathbb{S}^1$ . Orient all 2-simplices of  $S$  as before and let  $\gamma$  be their sum. Orient the 1-simplices arbitrarily. Once more, Statements 1 and 2 from the previous proof hold for the same reason as before. Since  $A$  is the wedge sum of two circles again, 3 holds again. However, condition 4 needs to be modified:

$$4. \partial\gamma = 2z_1.$$

This result can be obtained via a direct calculation similar from what we did before.

By 1 and 3 we know that every 1-cycle of  $S$  is homologous to a cycle of the form  $c = nw_1 + mz_1$ . If  $c$  is a boundary for some  $d$ , then 2 implies  $d = p\gamma$ . Thus,  $\partial d = 2pz_1$ . Therefore  $nw_1 + mz_1$  bounds if and only if  $m$  is even and  $n$  is zero. Thus,

$$H_1(S) \cong \mathbb{Z} \oplus \mathbb{Z}_2$$

The cycle  $z_1$  represents the torsion element, and  $w_1$  represents a generator of the infinite cyclic group  $H_1(S)/T_1(S)$ .

For the second homology group, note that any 2-cycle  $d$  of  $S$  must be of the form  $p\gamma$  by 2. 4 implies that  $p\gamma$  is not a cycle, hence

$$H_2(S) = 0.$$

□

Sometimes it is more convenient to use a slightly different kind of homology, the so called *reduced* homology. The following definition is taken from Munkres' book [4, p. 43].

**Definition 2.16.** Let  $\epsilon$  be the surjective homomorphism defined by  $\epsilon(v) = 1$  for each vertex  $v$  of  $K$ . If  $c$  is a 0-chain,  $\epsilon(c)$  equals the sum of the values of  $c$  on the vertices of  $K$ . The map  $\epsilon$  is called an augmentation map for  $C_0(K)$ . Since  $\epsilon(\partial d) = 0$  for all 1-chains  $d$ , we may consider the augmented chain complex

$$\dots \xrightarrow{\partial_2} C_1(K) \xrightarrow{\partial_1} C_0(K) \xrightarrow{\epsilon} \mathbb{Z}$$

This gives rise to the reduced homology groups

$$\tilde{H}_{n>0} = \ker \partial_n / \operatorname{im} \partial_{n+1} \quad \text{and} \quad \tilde{H}_0(K) = \ker \epsilon / \operatorname{im} \partial_1$$

We note that reduced and unreduced homology coincide for all groups except  $H_0(K)$ . We further note<sup>7</sup> that

$$H_0(K) \cong \tilde{H}_0(K) \oplus \mathbb{Z}$$

**Definition 2.17.** A chain map  $\Phi : \mathcal{C}_\bullet \rightarrow \mathcal{C}'_\bullet$  between augmented chain complexes is said to be augmentation-preserving if

$$\epsilon' \circ \Phi_0 = \epsilon.$$

### 3 Simplicial Homology Groups with $\mathbb{Z}/2\mathbb{Z}$ Coefficients

Let us remind ourselves of the definition for  $p$ -chains (Definition 2.3):

Let  $K$  be a simplicial complex. A  **$p$ -chain** on  $K$  is a function  $c$  from the set of oriented  $p$ -simplices of  $K$  to the integers such that:

1.  $c(\sigma) = -c(\sigma')$  if  $\sigma$  and  $\sigma'$  are opposite orientations of the same simplex.
2.  $c(\sigma) = 0$  for all but finitely many oriented  $p$ -simplices  $\sigma$ .

There is actually no reason (other than our familiarity with it) to restrict ourselves to the integers here. In fact, the same statements hold true for any abelian group  $G$  and it can be helpful to consider other groups than the integers. To denote the change of our underlying group, we use the notation

$$C_n(K; G) \quad \text{and} \quad H_n(K; G)$$

for the group of chains and the homology group of  $K$  with coefficients in  $G$ .

Since the group of chains with integer coefficients  $C_n(K; \mathbb{Z}) = C_n(K)$  merely consists of linear combinations of elementary chains with integer coefficients, there is a neat way to derive  $C_n(K; G)$  if  $C_n(K; \mathbb{Z})$  is already known. We find that

$$C_n(K; G) \simeq C_n(K; \mathbb{Z}) \otimes_{\mathbb{Z}} G,$$

which leads to many interesting phenomena. The same holds for homology groups if the coefficient ring is a field of characteristic zero.

A special case is the coefficient ring  $\mathbb{Z}/2\mathbb{Z}$ , since here  $-1 = 1$ . Hence, we no longer have to worry about orientation. Therefore, this ring is often used if the considered manifolds might or might not be orientable.

<sup>7</sup>For a proof of this statement see [4, p. 43]

**Examples 3.1.** We shall review the examples from the previous chapter, namely the Torus and the Klein bottle. With the same argument we see that

$$\begin{aligned} H_1(T; \mathbb{Z}_2) &\cong \mathbb{Z}_2 \otimes \mathbb{Z}_2 \\ H_2(T; \mathbb{Z}_2) &\cong \mathbb{Z}_2. \end{aligned}$$

For the Klein bottle  $S$ , the argument needs to be changed slightly. With  $\mathbb{Z}_2$  coefficients, the basic 2-chain  $\gamma$ , which is the sum of the 2-simplices of  $S$ , has boundary zero. This leads to the conclusion that

$$\begin{aligned} H_1(S; \mathbb{Z}_2) &\cong \mathbb{Z}_2 \oplus \mathbb{Z}_2 \\ H_2(S; \mathbb{Z}_2) &\cong \mathbb{Z}_2 \end{aligned}$$

More generally, one can show that Homology with  $\mathbb{Z}_2$  coefficients does not distinguish between orientable and non-orientable surfaces of genus  $g$ .

## 4 Functoriality Property

We will now explore how homotopy behaves under continuous functions. We will begin with the following definition and lemma from Munkres' book [4, lemma 12.1, p. 62]:

**Definition 4.1.** Let  $f : K \rightarrow L$  be a simplicial map. If  $v_0 \dots v_p$  is a simplex of  $K$ , then the points  $f(v_0) \dots f(v_p)$  span a simplex of  $L$ . we define a homomorphism  $f_\# : C_p(K) \rightarrow C_p(L)$  by defining it on oriented simplices as follows:

$$f_\#([v_0, \dots, v_p]) = \begin{cases} [f(v_0), \dots, f(v_p)], & \text{if } f(v_0), \dots, f(v_p) \text{ are distinct} \\ 0, & \text{otherwise} \end{cases}$$

The family  $\{f_\#\}$  is called the chain map induced by the simplicial map  $f$ .

This gives rise to the following diagram:

$$\begin{array}{ccccccc} \dots & \xrightarrow{\partial} & C_p(K) & \xrightarrow{\partial} & C_{p-1}(K) & \xrightarrow{\partial} & C_{p-2}(K) \xrightarrow{\partial} \dots \\ & & \downarrow f_\# & & \downarrow f_\# & & \downarrow f_\# \\ \dots & \xrightarrow{\partial} & C_p(L) & \xrightarrow{\partial} & C_{p-1}(L) & \xrightarrow{\partial} & C_{p-2}(L) \xrightarrow{\partial} \dots \end{array}$$

This of course raises the question whether this diagram commutes or not.

**Lemma 4.2.** *The homomorphism  $f_\#$  commutes with  $\partial$ ; therefore  $f_\#$  induces a homomorphism  $f_* : H_p(K) \rightarrow H_p(L)$*

*Proof.* Let  $\tau$  denote the simplex of  $L$  that is spanned by  $f(v_0), \dots, f(v_p)$ . We need to check

$$\partial f_{\#}([v_0, \dots, v_p]) = f_{\#}(\partial[v_0, \dots, v_p]) \quad (1)$$

**Case 1**  $\dim \tau = p$ : Clearly, this requires  $f(v_0), \dots, f(v_p)$  to be distinct. Therefore the statement follows directly from the definitions.

**Case 2**  $\dim \tau \leq p - 2$ : Here, the left side of (1) vanishes because  $f(v_0), \dots, f(v_p)$  are not distinct. The right side also vanishes, since for every  $i$ , at least two of the points  $f(v_0), \dots, \hat{f}(v_i), \dots, f(v_p)$  are the same.

**Case 3**  $\dim \tau = p - 1$ : We will assume the following ordering of vertices:

$$f(v_0) = f(v_1), \quad \text{and} \quad f(v_1), \dots, f(v_p) \text{ are distinct.} \quad (2)$$

Similarly, to the previous case, the left side of (1) vanishes and the right side reads

$$[f(v_1)f(v_2), \dots, f(v_p)] - [f(v_0), f(v_2), \dots, f(v_p)].$$

By (2) this also vanishes.

To show the second part of the lemma, we need to understand how  $f_{\#}$  acts on boundaries and cycles. Let  $c$  be an arbitrary cycle of  $K$ , i.e.  $\partial c = 0$ . Then by (1), we find  $\partial f_{\#}(c) = f_{\#}(\partial c) = f_{\#}(0) = 0$ .

Now, let  $b$  be an arbitrary boundary, i.e. there exists some  $d$  with  $b = \partial d$ . Then,  $f_{\#}(b) = f_{\#}(\partial d) = \partial f_{\#}(d)$ .

We have thereby shown that  $f_{\#}$  maps boundaries (cycles) of  $K$  to boundaries (cycles) of  $L$ .  $\square$

With this in mind we can now state the functional properties of these homomorphisms. We do this by following Munkres' book [4, Theorem 12.2, p. 53] once more.

**Theorem 4.3** (functorial properties I).

1. Let  $\text{id} : K \rightarrow K$  be the identity simplicial map. Then  $\text{id}_{\#} : H_p(K) \rightarrow H_p(K)$  is the identity homomorphism.
2. Let  $f : K \rightarrow L$  and  $g : L \rightarrow M$  be simplicial maps. Then  $(g \circ f)_{\#} = g_{\#} \circ f_{\#}$ ; That is, the following diagram commutes:

$$\begin{array}{ccc} H_p(K) & \xrightarrow{(g \circ f)_{\#}} & H_p(M) \\ & \searrow f_{\#} \quad \nearrow g_{\#} & \\ & H_p(L) & \end{array}$$

*Proof.* The first part of the Theorem is pretty obvious. The second part follows immediately from  $(g_{\#} \circ f_{\#}) = (g \circ f)_{\#}$ . To see this, we shall consider vertices  $v_0, \dots, v_p$  that span a simplex in  $K$ . Then by definition

$$f_{\#}([v_0, \dots, v_p]) = \begin{cases} [f(v_0), \dots, f(v_p)], & \text{if } f(v_0), \dots, f(v_p) \text{ are distinct,} \\ 0, & \text{otherwise} \end{cases}$$

Thus,

$$\begin{aligned} g_{\#} \circ f_{\#}([v_0, \dots, v_p]) &= \begin{cases} [g \circ f(v_0), \dots, g \circ f(v_p)], & \text{if } g \circ f(v_0), \dots, g \circ f(v_p) \text{ are distinct,} \\ 0, & \text{if } g \circ f(v_0), \dots, g \circ f(v_p) \text{ aren't distinct} \\ 0, & \text{if } f_{\#}([v_0, \dots, v_p]) = 0 \end{cases} \\ &= \begin{cases} [g \circ f(v_0), \dots, g \circ f(v_p)], & \text{if } g \circ f(v_0), \dots, g \circ f(v_p) \text{ are distinct,} \\ 0, & \text{otherwise} \end{cases} \\ &= (g \circ f)_{\#}([v_0, \dots, v_p]) \quad \square \end{aligned}$$

**Corollary 4.4.** *Let  $f : K \rightarrow L$  be a bijective simplicial map such that its inverse is also a simplicial map. Then*

$$\forall p \geq 0 : \quad H_p(K) \cong H_p(L)$$

□

This already gives the main Idea for the next section.

Let us remind ourselves of the general simplicial approximation theorem, as it can be found in Munkres' book [4, Thm. 16.5, p. 85]:

**Theorem 4.5** (The general simplicial approximation theorem). *Let  $K$  and  $L$  be complexes; let  $h : |K| \rightarrow |L|$  be a continuous map. There exists a subdivision  $K'$  of  $K$  such that  $h$  has a simplicial approximation  $f : K' \rightarrow L$ .*

We will further need the following definition again for Munkres' book [4, p. 100]:

**Definition 4.6.** Let  $K$  and  $L$  be simplicial complexes; let  $h : |K| \rightarrow |L|$  be a continuous map. Choose a subdivision  $K'$  of  $K$  such that  $h$  has a simplicial approximation  $f : K' \rightarrow L$  (such exists by virtue of the previous theorem). Let  $\lambda : C_{\bullet}(K) \rightarrow C_{\bullet}(K')$  be the subdivision operator. We define the homomorphism induced by  $h$

$$h_* : H_p(K) \rightarrow H_p(L)$$

via

$$h_* = f_* \circ \lambda_*$$

Since this definition involves several choices, we need to make sure, that the resulting homomorphism isn't dependent on these choices. We do this in two steps. Firstly, notice that for some choice of a subdivision  $K'$  two simplicial approximations, then these are contiguous and therefore induce the same homomorphism  $f_* \equiv g_*$  (see Theorems 5.7 and 5.9).

Let  $\iota : K' \rightarrow K$  be a simplicial approximation to the identity map of  $K$ , then  $\lambda_* = (g_*)^{-1}$ , hence

$$h_* = f_* \circ (g_*)^{-1}$$

Secondly, we will now use this to show that  $h_*$  doesn't depend on the choice of subdivision  $K'$  either. Let  $K''$  be another subdivision of  $K$  such that  $h$  has a simplicial approximation mapping  $K''$  to  $L$ . We will see that the induced homomorphism  $h_*$  does not change if we use substitute  $K$  with  $K''$  in its definition.

We will first explore the special case that  $|K|$  has a simplicial approximation  $k : K'' \rightarrow K'$

$$\begin{array}{ccc} & & K \\ & \nearrow g & \\ K'' & \xrightarrow{k} & K' \\ & \searrow f & \\ & & L \end{array}$$

Let  $h'_*$  be the induced homomorphism defined via  $K''$ . We can then write

$$h'_*(f \circ k)_* \circ (g \circ k)_*^{-1} = (f_* \circ k_*) \circ (g_* \circ k_*)^{-1} = f_* \circ g_*^{-1} = g_* \circ \lambda_* = h_*$$

We generalize this method by considering a subdivision  $K'''$  of  $K$  such that the identity map has simplicial approximations

$$k_1 : K''' \rightarrow K' \quad \text{and} \quad k_2 : K''' \rightarrow K''.$$

We can now use this subdivision to construct a homomorphism  $h''_*$ . By our previous work, we already know that

$$h'_* = h''_* = h_*$$

We are now able to generalize Theorem 4.3

**Theorem 4.7** (functorial properties II). *The identity map  $id : |K| \rightarrow |K|$  induces the identity homomorphism  $i_* : H_p(K) \rightarrow H_p(K)$ . If  $h : |K| \rightarrow |L|$  and  $k : |L| \rightarrow |M|$  are continuous maps, then  $(k \circ h)_* = k_* \circ h_*$ .*

*Proof.* The first part is elementary. For the second part, choose simplicial approximations as follows:

$$\begin{array}{l|l} f_0 : L' \rightarrow M & \text{simplicial approximation to } k \\ g_0 : L' \rightarrow L & \text{simplicial approximation to the identity on } |L| \\ f_1 : K' \rightarrow L' & \text{simplicial approximation to } h \\ g_1 : K' \rightarrow K & \text{simplicial approximation to the identity on } |K| \end{array}$$

$$|K| \xrightarrow{h} |L| \xrightarrow{k} |M|$$

$$\begin{array}{ccccc} & & K & & L & & M \\ & & \uparrow & & \uparrow & \nearrow f_0 & \\ & & g_1 & & g_0 & & \\ & & K' & \nearrow f_1 & L' & & \end{array}$$

With these choices,  $f_0 \circ f_1$  is a simplicial approximation to  $k \circ h$ , hence

$$(k \circ h)_* = (f_0 \circ f_1)_* \circ (g_1)_*^{-1}$$

Since  $g_0 \circ f_1$  is a simplicial approximation to  $h$ , have

$$h_* = (g_0 \circ f_1)_* \circ (g_1)_*^{-1} \quad \text{and} \quad k_* = (f_0)_* \circ (g_0)_*^{-1}$$

Combining these results and applying Theorem 4.3 we obtain

$$(k \circ h)_* = k_* \circ h_*$$

as desired. □

## 5 Homotopy Invariance of Simplicial Homology

We have arrived at what is probably the most important chapter of this paper. In section 1 we already mentioned that we can use (simplicial) homology groups to show that two spaces are not homotopic (or homeomorphic). However, so far we never explained why non-isomorphic homology groups imply that. We need to show that homology groups are topological invariants, i.e. that homotopic spaces have isomorphic homology groups.

We already saw a very special case in Corollary 4.4. As we will see shortly, the main idea is essentially the same for a more general statement

**Corollary 5.1.** *Let  $f : |K| \rightarrow |L|$  be a homeomorphism, then  $f_* : H_n(K) \rightarrow H_n(L)$  is an isomorphism.*  $\square$

We have discovered the topological invariance of homology groups. However, there is an even stronger statement to be made here. As we will see in the following, homology groups are not only invariant under homeomorphisms, but only depend on the homotopy type.

Recall the definition of homotopy, taken from Munkres [4, p. 94]:

**Definition 5.2.** If  $X$  and  $Y$  are topological spaces, two continuous maps  $h, k : X \rightarrow Y$  are said to be homotopic if there is a continuous map

$$F : X \times I \rightarrow Y$$

such that  $F(x, 0) = h(x)$  and  $F(x, 1) = k(x)$  for all  $x \in X$ . If  $h$  and  $k$  are homotopic, we write  $h \simeq k$ . The map  $F$  is called a homotopy of  $h$  to  $k$ .

**Definition 5.3.** Two spaces  $X$  and  $Y$  are said to be homotopy equivalent, or to have the same homotopy type, if there are maps

$$f : X \rightarrow Y \quad \text{and} \quad g : Y \rightarrow X$$

such that  $g \circ f \simeq i_X$  and  $f \circ g \simeq i_Y$ . The maps  $f$  and  $g$  are often called homotopy equivalences, and  $g$  is said to be the homotopy inverse to  $f$ .

The main task is to prove the following statement:

**Theorem 5.4.** *If  $f, g : |K| \rightarrow |L|$  are homotopic maps then  $f_* = g_* : H_q(K) \rightarrow H_q(L)$  for all  $q$*

Once we have obtained this result, the homotopy invariance follows easily [see 1, Theorem 8.11]:

**Corollary 5.5.** *If two polyhedra  $K$  and  $L$  are homotopy equivalent, then their homology groups are isomorphic  $H_n(X) \cong H_n(Y)$  in all dimensions.*

*Proof.* Let  $f, g$  denote the maps as described in the definition of homotopy equivalence, i.e. let  $g$  be the homotopy inverse of  $f$ . Consider the following Diagram:

$$H_q(K) \xrightarrow{f_*} H_q(L) \xrightarrow{g_*} H_q(K)$$

$$H_q(L) \xrightarrow{g_*} H_q(K) \xrightarrow{f_*} H_q(L)$$

Then

$$f_* \circ g_* = \underbrace{(f \circ g)}_{\simeq i_K}_* = (i_K)_* = (i_*)_{H_q(K)}$$

and

$$g_* \circ f_* = \underbrace{(g \circ f)}_{\simeq i_L}_* = (i_L)_* = (i_*)_{H_q(L)}$$

Therefore,  $f_*$  and  $g_*$  are isomorphisms and  $f_* = (g_*)^{-1}$ .  $\square$

With the results from the previous chapter we can conclude that for any compact triangulable space, we can choose a triangulation  $t : |K| \rightarrow X$  without loss of generality (i.e. it doesn't matter which triangulation we choose up to isomorphism) and use it to define the homology groups of  $X$  as  $H_q(X) := H_q(K)$ .

Before we can get started with that we need some preliminary definitions and results:

**Definition 5.6.** Let  $f, g : K \rightarrow L$  be simplicial maps. Suppose that for each  $p$ , one has a homomorphism

$$D : C_p(K) \rightarrow C_{p+1}(L)$$

satisfying the equation

$$\partial D + D \partial = g_\# - f_\#.$$

Then  $D$  is said to be a chain homotopy between  $f_\#$  and  $g_\#$ . Note that the diagram

$$\begin{array}{ccc} & & C_{p+1}(L) \\ & \nearrow D_p & \downarrow \partial \\ C_p(K) & \xrightarrow{(g_\#)_p} & C_p(L) \\ & \searrow (f_\#)_p & \\ & & C_{p-1}(K) \\ & \nwarrow D_{p-1} & \end{array}$$

is not commutative.

**Theorem 5.7.** If there is a chain homotopy between  $f_\#$  and  $g_\#$  then the induced homomorphisms  $f_*$  and  $g_*$  are equal.

*Proof.* Let  $c$  be a  $p$ -cycle of  $K$ . Then

$$g_\#(c) - f_\#(c) = \partial Dc + D\partial c = \partial Dc + 0.$$

That means that  $f_\#$  and  $g_\#$  differ only by a boundary. Therefore they are in the same homology class, i.e.  $f_*(c) = g_*(c)$ .  $\square$

**Definition 5.8.** Given two simplicial maps  $f, g : K \rightarrow L$ , these maps are said to be contiguous if for each simplex  $v_0 \dots v_p$  of  $K$ , the points

$$f(v_0), \dots, f(v_p), g(v_0), \dots, g(v_p)$$

span a simplex of  $L$ .

**Theorem 5.9.** If  $f, g : K \rightarrow L$  are contiguous simplicial maps, then there is a chain homotopy between  $f_\#$  and  $g_\#$ .

*Proof.* Let  $\sigma = (v_0, \dots, v_p) \subset K$  and  $L(\sigma) = (f(v_0), \dots, f(v_p), g(v_0), \dots, g(v_p)) \subset L$ . Then

1.  $L(\sigma)$  is a nonempty, and  $\tilde{H}_n(L(\sigma)) = 0$  for  $n \geq 0$ .
2. If  $s$  is a face of  $\sigma$ , then  $L(s) \subset L(\sigma)$ .
3. For each oriented simplex  $\sigma$ , the chains  $f_\#(\sigma)$  and  $g_\#(\sigma)$  are zero on every simplex not in  $L(\sigma)$ .

We will now construct the chain homotopy  $D : C_p(K) \rightarrow C_{p+1}(L)$  by induction on  $p$ . For each  $\sigma$ , the chain  $D\sigma$  will vanish on any simplex not contained in  $L(\sigma)$ .

Let  $p = 0$  and  $v$  be a vertex of  $K$ . Because  $f_\#$  and  $g_\#$  preserve augmentation,

$$\epsilon(g_\#(v) - f_\#(v)) = 1 - 1 = 0.$$

Thus  $g_\#(v) - f_\#(v)$  represents an element of the reduced homology group  $\tilde{H}_0(L(v))$ . Because this group vanishes, we can choose a 1-chain  $Dv$  of  $L$  carried by the subcomplex  $L(v)$  such that

$$\partial(Dv) = g_\#(v) - f_\#(v)$$

Then  $\partial Dv + D\partial v = \partial Dv + 0 = g_\#(v) - f_\#(v)$ , as desired. Define  $D$  in this way for each vertex of  $K$ .

Now suppose  $D$  is defined in dimensions less than  $p$ , such that for each oriented simplex  $s$  of dimension less than  $p$ , the chain  $Ds$  is carried by  $L(s)$ , and such that

$$\partial Ds + D\partial s = g_\#(s) - f_\#(s)$$

Let  $\sigma$  be an oriented simplex of dimension  $p$ . We wish to define  $D\sigma$  so that  $\partial(D\sigma)$  equals the chain

$$c = g_\#(\sigma) - f_\#(\sigma) - D\partial\sigma$$

Note that  $c$  is a well-defined chain;  $D\partial\sigma$  is defined because  $\partial\sigma$  has dimension  $p - 1$ . Furthermore,  $c$  is a cycle, for we compute

$$\begin{aligned} \partial c &= \partial g_\#(\sigma) - \partial f_\#(\sigma) - \partial D(\partial\sigma) \\ &= \partial g_\#(\sigma) - \partial f_\#(\sigma) - [g_\#(\partial\sigma) - f_\#(\partial\sigma) - D\partial(\partial\sigma)] \end{aligned}$$

applying the induction hypothesis to the  $p - 1$  chain  $\partial\sigma$ . Using the fact that  $\partial \circ \partial = 0$ , we see that  $\partial c = 0$ .

Finally, we note that  $c$  is carried by  $L(\sigma)$ , and since  $\tilde{H}_p(L(\sigma)) = 0$ , we can choose a  $p + 1$  chain  $D\sigma$  carried by  $L(\sigma)$  such that

$$\partial D\sigma = c = g_{\#}(\sigma) - f_{\#}(\sigma) - D\partial\sigma$$

We then define  $D(-\sigma) = -D(\sigma)$ . We repeat this process for each  $p$ -simplex  $\sigma$  of  $K$ ; then we have the required chain homotopy  $D$  in dimension  $p$ . The theorem follows.  $\square$

*Proof of Theorem 5.4.* We will state the the following results without proof:

**Fact:** If  $f, g : |K| \rightarrow |L|$  are homotopic maps we can find a barycentric subdivision  $K^m$  and a sequence of simplicial maps  $s_1, \dots, s_n : |K^m| \rightarrow |L|$  such that  $s_1$  simplicially approximates  $f$ ,  $s, n$  simplicially approximates  $g$ , and each pair  $s_i, s_{i+1}$  is contiguous.

Let  $\lambda_*$  be the homomorphism induced by the subdivision operator. With the results above, we find

$$f_* = s_{1*}\lambda_* = s_{2*}\lambda_* = \dots = s_{n*}\lambda_* = g_*$$

$\square$
